

PERFORMANCE TEST

Auto Ticket Classification using Flow Designer

1. Purpose of the Performance Test

The performance test is conducted to verify that the ServiceNow Flow Designer automation processes incident tickets correctly and efficiently. The test focuses on trigger execution, classification accuracy, automatic record updates, and the ability of the workflow to handle different types of IT incidents.

2. Test Objectives

- Verify that the flow is triggered when a relevant incident is created.
- Verify that the configured conditions identify the correct issue type.
- Verify that the incident classification is updated automatically.
- Verify that different incident descriptions are handled consistently.
- Identify any incorrect, missing, or delayed classification results.

3. Performance Test Cases

Test ID	Test Input / Scenario	Expected Result	Status
PT-01	Create an incident: "Wi-Fi is not connecting in the computer lab."	Flow triggers and classifies the incident as Network.	Pass
PT-02	Create an incident: "I forgot my computer login password."	Flow triggers and classifies the incident as Access / Account.	Pass
PT-03	Create an incident: "The projector is not working."	Flow triggers and classifies the incident as Hardware.	Pass
PT-04	Create an incident: "My computer is running very slowly."	Flow triggers and classifies the incident as Performance.	Pass
PT-05	Create an incident related to an application/software problem.	Flow identifies the configured Software classification.	Pass
PT-06	Create multiple incidents with different issue descriptions.	Each incident is processed according to its matching rule.	Pass

4. Test Procedure

1. Log in to the ServiceNow Developer Instance.
2. Open the Incident Management module.
3. Create a new incident with a representative issue description.
4. Submit the incident and allow the Flow Designer workflow to execute.
5. Open the incident record and verify the automatically updated classification.
6. Repeat the process using different incident types.
7. Record the observed result for each test case.

5. Performance Evaluation Criteria

Criteria	Expected Performance
Trigger execution	Flow should execute automatically for the configured incident trigger.
Classification accuracy	Incident should receive the classification corresponding to the configured rule.

Criteria	Expected Performance
Record update	The incident record should reflect the automated classification.
Consistency	Similar incident descriptions should produce consistent results.
Automation	No manual classification should be required after incident creation.

6. Test Result Summary

The performance test verifies that the Flow Designer automation can process representative IT incidents and apply the configured classification rules automatically. Successful execution demonstrates that the workflow reduces manual classification effort and provides consistent results.

7. Conclusion

The automated ticket classification workflow meets the primary performance expectations for the project. The flow can be tested with different incident types and the resulting classification can be verified directly on the ServiceNow incident record. The test also provides a basis for future improvements such as automatic assignment, notification, escalation, and more advanced classification logic.
